Differences between API implementations

In this article

The browser extensions API is an [emerging standard](#). As a result, while it is supported by most major browsers – including Firefox, Chrome, Edge, and Opera – there are differences between the various implementations. This means some changes may be necessary to implement your extension for multiple browsers.

[Asynchronous event handling](#)

Among the various browsers supporting the extensions API, Firefox is the most compliant with the emerging standard and, therefore, is your best place to start when developing browser extensions.

[Manifest keys](#)

The differences between browsers' API implementations fall into four areas: namespace, asynchronous event handling, API coverage, and manifest keys.

Browser extensions

► [Getting started](#)

You reference all extensions API functions using a namespace. For example, `browser.alarms.create({delayInMinutes});` creates an alarm in Firefox that goes off after the time specified in `delayInMinutes`.

[JavaScript APIs](#)

There are two API namespaces in use:

[Background scripts](#)

- `chrome` used in Chrome, Edge, and Opera.

[Match patterns](#)

- `browser` used in Firefox and Safari.

[Internationalization](#)

Asynchronous event handling

JavaScript provides several ways to handle asynchronous events. The proposed extensions API standard is to use promises. The promises approach offers significant advantages when dealing with chained asynchronous event calls.

[Differences between API implementations](#)

Firefox and Safari implement promises for the extensions API. All other browsers use callbacks. In Manifest V3, Chrome, Edge, and Opera provided for [promises](#) on most appropriate methods. (cf. [Chrome bug 328932](#))

► [User interface](#)

If you are unfamiliar with how JavaScript can handle asynchronous events or promises, look at [Getting to know asynchronous JavaScript: Callbacks, Promises and Async/Await](#) or the MDN [Using promises](#) page.

API coverage

► [Extension Workshop](#)

The differences in the extensions API function implementations among the browsers fall into three broad categories:

[Contact us](#)

► [Channels](#)

- Lack of support for an entire function.
- Variations in the support for features within a function. For example, at the time of writing, Firefox doesn't support the [notification](#) function method `onButtonClicked`, while Firefox is the only browser that supports `onShown`.
- Proprietary functions supporting browser-specific features. For example, at the time of writing, containers is a Firefox-specific feature supported by the [contextualIdentities](#) function.

Manifest keys

The differences in the supported [manifest.json keys](#) among the browsers fall broadly into two categories:

- Extension information attributes. For example, at the time of writing, Firefox and Opera include the [developer](#) key (in addition to the

[author](#) key) to record details about the extension developer.

- Extension features. For example, at the time of writing, only Firefox supports the [protocol_handlers](#) key (which registers web-based protocol handlers, applications that know how to handle particular types of links).

More information

You can find more detailed information about the differences in the supported browser extensions API features in:
